Goals

Build systems are designed to meet several goals:

- Integrate all the software components into a workspace and a working image
- Be able to easily reproduce a build

Actually, they build software using the existing building system shipped within each component.

Several solutions: Yocto, Buildroot, ...

Originally, Google came up with its own solution for Android, that never relies on other build systems, except for GNU/Make

- It allows to rely on very few tools, and to control every software component in a consistent way.
- But it also means that when you have to import a new component, you have to rewrite the whole Makefile to build it
- In AOSP sources, everything in the `build` directory

Even if ninja builds faster than make, makefile loading is still horrible.

A new weapon : [soong](#)

- File extension : `.bp`
- AOSP main manifest : `Android.bp` at the root of the sources
- Syntax intentionally similar to Bazel
- It takes only 5 seconds to regenerate the main manifest instead of 1-2 minutes for an `Android.mk`.

Google plans to abandon make but not tomorrow:

- Still 3593 Android.mk in Oreo sources
- Only 1415 soong files.

Build System Configuration

The Android build system is not much configurable compared to other build systems, but it is possible to modify to some extent.

You can:

- choose what product you want to build,
- add extra flags for the C compiler,
- have a given package built with debug options,
- specify the output directory, ...

This is done either through the `lunch` command or through a `buildspec.mk` file

`lunch` is a shell function defined in `build/envsetup.sh`

It is the easiest way to configure a build.

Without any argument, it will ask to choose among a list of known “combos”, or launch it with the desired combos as argument.

It sets the environment variables needed for the build.

You can declare new combos through the `add_lunch_combo` command

Combo definition

```
<product name>-<build variant>    e.g: full_fugu-userdebug
```

Check your configuration

```
printconfig
```

Kernels

- **HOST_ARCH:** x86 or x86_64
- **HOST_OS:** Generally linux
- **HOST_BUILD_TYPE:** Build properties for the host, either `release` or `debug`.
- **BUILD_ID:**
 - Specify the branch name and/or a release candidate.
 - It must be a single word, and is capitalized by convention.

If you have only one product or you want to do more fine-grained configuration, `buildspec.mk` file is here for that.

Place it at the top of the sources, and it will be used by the build system to get its configuration instead of relying on the environment variables.

It offers more variables to modify:

- compiling a given module with debugging symbols,
- add C compiler flags,
- change the output directory, etc.

A sample is available in `build/make/buildspec.mk.default`, with lots of comments on the various variables.

All the output is generated in the `out/` directory, outside of the source code directory

This directory contains mostly two subdirectories:

- `host/`
- `target/`

These directories contain all the objects files compiled during the build process.

It generates the system images in the `out/target/product/<device_name>/` directory

These images are:

- boot.img** A basic Android image, containing only the needed components to boot: a kernel image and a minimal system
- system.img** The remaining parts of Android. Much bigger, it contains most of the framework, applications and daemons
- userdata.img** A partition that will hold the user generated content. Mostly empty at compilation.
- recovery.img** A recovery image that allows to be able to debug or restore the system when something nasty happened.

Never ever

Do not use these recovery images. Use [twrp](#).

The boot images are actually an Android-specific format, that holds most of what the bootloader expects

They contains useful information:

- the kernel command line
- where to load the kernel
- the kernel image,
- an optional initramfs

A custom `mkbootimg` tool is used by Android to generate these images at compilation time from the kernel and the system it's generating.

We can tweak the behaviour of that tool from the build system configuration, that allows a great flexibility

Android
Build
System :
Basics

Build
System :
Advanced

Android
modules

Android
products

Kernels

Every component in Android is called a module.

Modules are defined across the entire tree through the `Android.mk` files.

The build system abstracts many details to make the creation of a module's Makefile as trivial as possible.

Of course, building a module that will be an Android application and building a static library will not require the same instructions, but these builds don't differ that much either.

Example

Android,
System
Approach

Alizée
Penel

Android
Build
System :
Basics

Build
System :
Advanced

Android
modules

Android
products

Kernels

```
LOCAL_PATH := $(call my-dir)
include $(CLEAR_VARS)
```

```
LOCAL_SRC_FILES = hello_world.c
LOCAL_MODULE = HelloWorld
```

```
LOCAL_MODULE_TAGS = optional
include $(BUILD_EXECUTABLE)
```

Module variable definitions

Android,
System
Approach

Alizée
Penel

Android
Build
System :
Basics

Build
System :
Advanced

Android
modules
Android
products

Kernels

LOCAL_PATH Tells the build system where the current module is

include \$(CLEAR_VARS) Cleans the previously declared

LOCAL_SRC_FILES Contains a list of all source files to be compiled

LOCAL_MODULE Sets the module name

LOCAL_MODULE_TAGS Defines the set of modules this module should belong to

include \$(BUILD_EXECUTABLE) Tells the build system to build this module as a binary

Example

Android,
System
Approach

Alizée
Penel

Android
Build
System :
Basics

Build
System :
Advanced

Android
modules

Android
products

Kernels

```
LOCAL_PATH := $(call my-dir)
include $(CLEAR_VARS)
```

```
LOCAL_MODULE_TAGS := optional
LOCAL_MODULE := configuration_files.txt
LOCAL_MODULE_CLASS := ETC
LOCAL_MODULE_PATH := $(TARGET_OUT_ETC)
LOCAL_SRC_FILES := $(LOCAL_MODULE)
```

```
include $(BUILD_PREBUILT)
```

Every module variable is prefixed by `LOCAL_*`.

The list of the variables cleared is in `build/make/core/clear_vars.mk`.

LOCAL_CFLAGS Extra C compiler flags to use to build the module

LOCAL_SHARED_LIBRARIES List of shared libraries this module depends on at compilation time

LOCAL_PACKAGE_NAME Equivalent to `LOCAL_MODULE` for Android packages

LOCAL_C_INCLUDES List of paths to extra headers used by this module

LOCAL_REQUIRED_MODULES Express that a given module depends on another at runtime, and therefore should be included in the image as well

Tags are used to define several sets of modules to be built through the build variant selected by `lunch`.

We have 3 build variants:

- **user**
 - Installs modules tagged with `optional`
 - Installs non-packaged modules that have no tags specified
 - `ro.secure = 1`
 - `ro.debuggable = 0`
 - ADB is disabled by default
- **userdebug** is `user`, except:
 - Also installs modules tagged with `debug`
 - `ro.debuggable = 1`
 - ADB is enabled by default

- `eng` is `userdebug`, plus
 - Installs modules tagged as `eng` and `development`
 - `ro.secure = 0`
 - `ro.kernel.android.checkjni = 1`

`LOCAL_MODULE_TAGS` can take many tags, separated by whitespace :

`user` Not allowed anymore in build system (since Lollipop).

`optional` Replace user tag, include module in each build.

`debug` Include module in userdebug builds.

`eng` Include module in eng builds.

`tests` Declare module as a test package

```
make tests dist
```

`samples` Declare module as a sample, never included

Kernels

In the `build/make/core/definitions.mk` file, you will find useful macros to use in the `Android.mk` file, that mostly allows you to:

- Find files: `all-makefiles-under`, `all-subdir-c-files`, etc.
- Transform them: `transform-c-to-o`, etc.
- Copy them: `copy-file-to-target`, etc.
- And some utilities: `my-dir`, `inherit-package`, etc.

All these macros should be called through Make's `call` command, possibly with arguments.

Want to create your own macro ?

Check in `build/make/core/definition.mk` first !

Kernels

This is a mechanism used by products to override resources already defined in the source tree, without modifying the original code.

Use the `DEVICE_PACKAGE_OVERLAYS` or `PRODUCT_PACKAGE_OVERLAYS` variables that you set to a path to a directory in your device folder.

This directory should contain a structure similar to the source tree one, with only the files that you want to override.

You will also need a `BoardConfig.mk` file along with the product definition.

While the product definition was mostly about the build system in itself, the board definition is more about the hardware.

However, this is poorly documented and sometimes ambiguous so you will probably have to dig into the `build/make/core/Makefile` at some point to see what a given variable does.

Android kernel
development

```
ifeq ($(TARGET_PREBUILT_KERNEL),)
    LOCAL_KERNEL := device/ti/panda/kernel
else
    LOCAL_KERNEL := $(TARGET_PREBUILT_KERNEL)
endif

PRODUCT_COPY_FILES := \
    $(LOCAL_KERNEL):kernel
```

AOSP has a kernel repository per device.

The complete list is [here](#)

Nowdays, a vanilla kernel for x86 architecture with Android features activated works. No need to use goldfish repository.

Clone must be aside AOSP source tree.

Toolchains

Kernels

Basics

Android kernel
development

- Goggle toolchains (prebuilts/gcc)
- Linaro's toolchains (for ARM only)

Kernel build

Android,
System
Approach

Alizée
Penel

Android
Build
System :
Basics

Build
System :
Advanced

Kernels

Basics

Android kernel
development

```
export ARCH=arm64
export CROSS_COMPILE=aarch64-linux-android-
cd hikey-linaro
git checkout -b android-hikey-linaro-4.1 origin/android-hikey-linaro-4.1
make hikey_defconfig
make
```

At the directory root, you will find `build.config.<arch>`.

Source it, run `make`.

To avoid the copy at each kernel new build, you can:

```
export TARGET_PREBUILT_KERNEL=<your_kernel_path>/arch/arm/boot/zImage-dtb
```

Android and kernel modules

Kernels

Basics

Android kernel
development

Before Oreo, Android did not support kernel modules : modules statically bundled in the kernel binary.

Thanks to Greg Kroah-Hartman help, Google did a great work about Android kernel supports.

[Documentation](#)

```
vendor_lkm_dir := device/$(vendor)/lkm-4.x
BOARD_VENDOR_KERNEL_MODULES := \  
    $(vendor_lkm_dir)/vendor_module_a.ko \  
    $(vendor_lkm_dir)/vendor_module_b.ko \  
    $(vendor_lkm_dir)/vendor_module_c.ko
```

Overlays can be use.
